

Software Development Unit 3.4

Anna Legaspi

I can respond appropriately to problems with multi-page websites.

The purpose of my website is to showcase myself as an artist including my art, information about me and a way to contact me including my socials. I couldn't condense all of this information in one web page, hence it was better to spread it across several pages:

- **Home** - the initial landing page of my website
- **Portfolio** - displays all my art work
- **About me** - a short summary of who I am as an artist
- **Contact** - ways to contact me and my socials

These pages need to be accessible anywhere in the website, therefore I needed to make sure it was available on every page. I created a section dedicated to navigation which holds the links to all four pages. It was a case of copy pasting the code over on all of the pages for the navigation, but it was still important to check all the links on every single page in case there was a broken link.

For instance, I needed to change the "About me.html" to "About_me.html". Adding the additional underscore meant that all the links on my website that meant to direct the user to the About me page were broken. I therefore needed to update the anchor tag on all four pages with the new and updated URL. Otherwise, this will create a bad link or a 404 error.

Please see the test I've created on a separate file which confirms the checks I've completed. Please also note that I've done a detailed test under Unit 3.2 on the links working which includes screenshots.
